Supplementary Note 1 - Exploratory Analysis of Moderators

Moderation Analyses by Participants and Setting

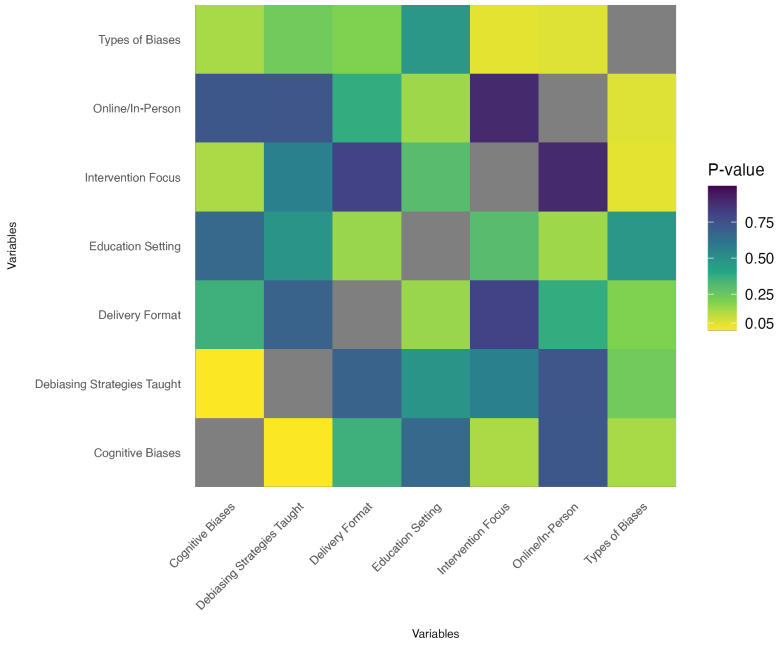
Age was not a significant moderator when comparing debiasing interventions to control conditions ($F(1,109) = 0.26$, $n_{\text{studies}} = 24$, $k_{\text{effect sizes}} = 111$, $p = 0.61$). Similarly, moderation effects were not significant for educational setting (e.g., schools or university; ($F(1,158) = 0.06$, $n_{\text{studies}} = 41$, $k_{\text{effect sizes}} = 160$, $p = 0.81$) or gender ($F(1,135) = 3.08$, $n_{\text{studies}} = 30$, $k_{\text{effect sizes}} = 137$, $p = 0.08$).

Associations Between Moderators

A heatmap depicting the relationships between categorical moderators is available below. We found that two pairs of moderators were confounded: (i) types of biases and intervention focus, and (ii) cognitive biases and debiasing strategies taught. We ran further analyses using both moderators at once; these moderators did not significantly impact our outcomes when controlling for the other moderator (Types of biases and intervention focus: $F(4,155) = 0.46$, $n_{\text{studies}} = 41$, $k_{\text{effect sizes}} = 160$, $p = 0.76$; cognitive biases and debiasing strategies: $F(9,123) = 1.92$, $n_{\text{studies}} = 36$, $k_{\text{effect sizes}} = 133$, $p = 0.06$).

Figure 1

Heatmap depicting relationships between categorical moderators



N = 37 studies. Colors represent p-values from pairwise chi-squared tests.
Note: p-values were calculated using two-tailed tests with no adjustments for multiple comparisons.

None of the continuous moderators (i.e., mean age, the percentage of female participants, and intervention duration) were significantly correlated. The correlation between mean age at the start of the study and the percentage of female participants was $r = -0.10$, $p = 0.67$. Similarly, the correlation between mean age at the start of the study and the intervention duration was $r = -0.08$, $p = 0.75$. Lastly, the correlation between the percentage of female participants and the intervention duration was $r = 0.16$, $p = 0.50$. These results suggest that there is no significant multicollinearity among the continuous moderators.

When comparing these continuous moderators to categorical moderators using ANOVAs, some of them had significant relationships. Mean age of participants was significantly correlated with education setting ($F(1, 17) = 6.42$, $p = 0.02$). This relationship is understandable, given that higher educational setting is associated with higher age. Mean age of participants was also significantly correlated with delivery format ($F(4, 14) = 3.12$, $p = 0.049$). In our dataset, the participants in the lower age group had more traditional training, whereas participants in the higher age group had more video-based interventions. The percentage of female participants was significantly correlated with intervention mode (online/in-person; $F(1, 17) = 9.05$, $p = 0.008$), which meant that in our dataset, the interventions with a higher percentage of female participants were more likely to be conducted in person rather than online.
